

Horse Management System

Every screen, and how it relates to the StudLib database

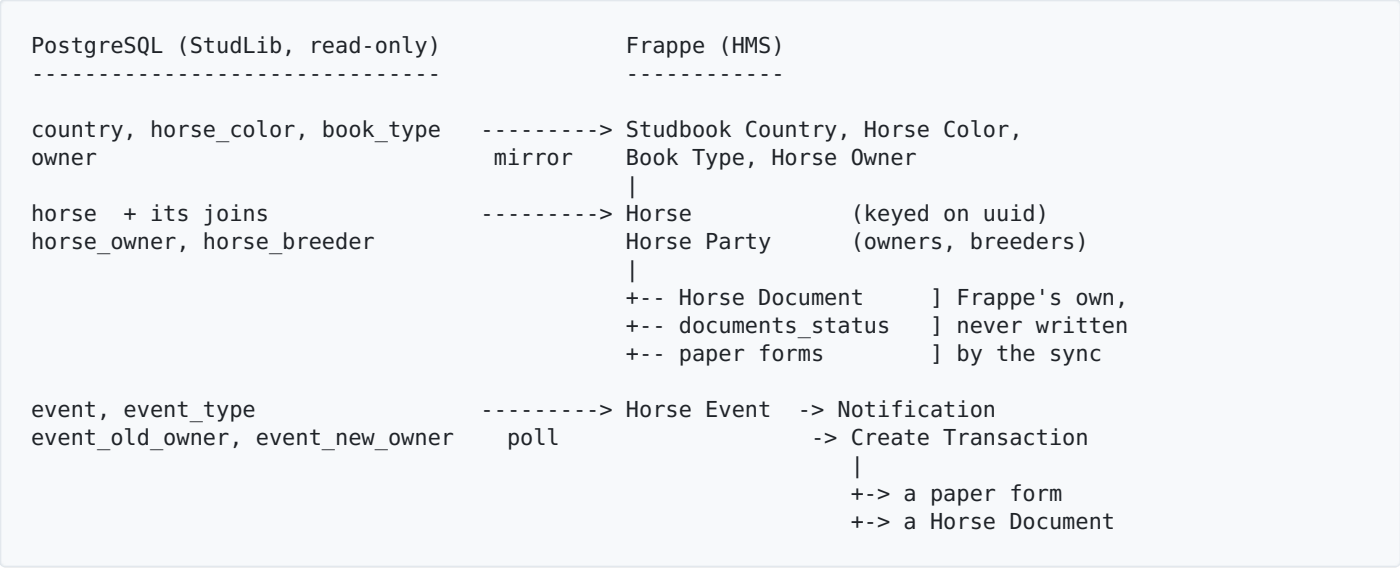

Frappe application `hms`

Studbook data specification 1.01

Generated from a live site — every figure is a real record.

How HMS and StudLib fit together

StudLib is the system of record for horses: identity, pedigree, ownership. HMS holds the same horses plus the things StudLib knows nothing about — scanned documents, completion status and the paper forms. HMS reads StudLib through a **read-only** Postgres role and never writes back.

Two pipelines, kept apart

The **horse sync** carries state. The **event poll** carries notices. They never cross: StudLib records a death event *and* writes the death date onto the horse, so the sync already has the fact — the event exists only to tell someone and to start the paperwork. An event handled wrongly therefore cannot corrupt a horse record.

Why the event poll looks backwards. Postgres hands out sequence values before a transaction commits, so a transaction holding event 500 can commit after one holding 505. A plain `id > watermark` would read 505, move past 500, and lose it forever. The poll therefore re-reads a window of 200 ids below the watermark and drops what it already has.

Who owns what

StudLib owns	HMS owns
names, registry ids, UELN, microchip, sex, colour, breed, strain, classification, registration status, all seven dates, studbook volume and page, sire and dam, owners and breeders, birthplace / import / export country	every Horse Document and its details, documents_status , the registration and change forms, Horse Events once they have been raised

The sync writes only the left column, so re-running it can never cost anyone an upload.

The field mapping

Every Horse field carries its StudLib column name, with two deliberate exceptions noted below.

StudLib column	Horse field	Note
name	name_en	Official registered name. <code>name</code> is Frappe's docname, hence the alias.
local_name	name_ar	The local-language name.
uuid	studbook_uuid	The sync key. Stable from creation, unlike the registry number.

registry_id	registry_id	Empty until the horse is registered.
status	status	Registration workflow: New Foal → ... → Register in Studbook.
sex	gender	Seven values, not three: Stallion, Broodmare, Cryptorchid and Monorchid too.
breed	breed	Arabian or Thoroughbred. Scopes colours and book types.
ueln	ueln_no	15-character international code.
transponder_code	microchip_no	ISO 11784/11785 microchip.
date_of_death	date_of_death	life_status is derived from it.
birthplace_country_id	birthplace_country	→ Studbook Country. Origin is derived from its Local flag.
color_id	color	→ Horse Color, which is breed-specific.
book_type_id	book_type	→ Book Type.
father_id / mother_id	sire / dam	→ Horse. Resolved in a second pass, so a foal read before its sire still links.
horse_owner (M:N)	owners	Child table. A horse may have several owners at once.
horse_breeder (M:N)	breeders	Child table. The dam's owners at foaling.
–	documents_status	Frappe's own. Never written by the sync.

1. The workspace

Everything starts here. The number cards and charts are ordinary Frappe dashboard records, so they read live counts out of the site rather than out of the studbook.

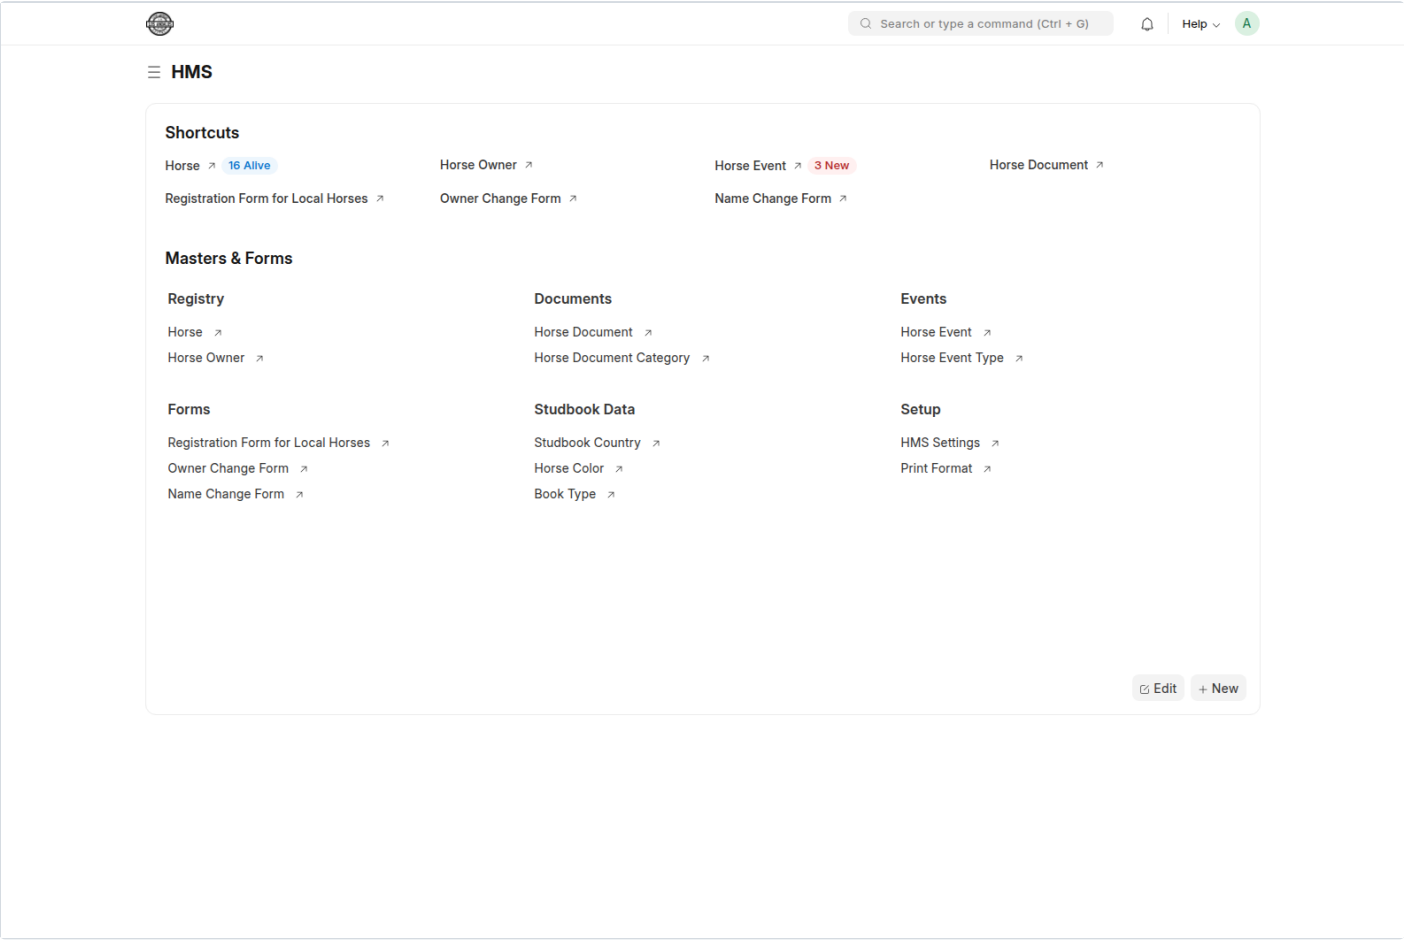

Figure 1. The HMS workspace. **New Events** counts studbook events nobody has acted on yet; **Documents Incomplete** counts horses still missing a required document. The link cards below group the whole app: Registry, Documents, Events, Forms, Studbook Data and Setup.

2. The horse registry

A Horse is a mirror of one row of the StudLib horse table. The sync writes it; nothing here is typed in by hand once a horse is coming from the studbook.

For comparison, use >5, <10 or =324. For ranges, use 5:10 (for values between 5 & 10).

18 of 18

Figure 3. The same records in report view, where the studbook's own fields are visible as columns: sex, registration status and origin.

3. A horse that came from the studbook

Bint Misr was read out of StudLib by the sync. Every field on the Identity and Studbook tabs is owned by the studbook and rewritten on each run; nothing on this horse was typed here.

Figure 4, 2 of 2. The Identity tab. **Registry ID** is StudLib's `registry_id`, **Studbook UUID** is its `uuid` — and the `uuid`, not the registry number, is what the sync matches on, because a foal has no registry number until it is registered. **Country of Origin** is greyed out because it is derived: StudLib has no origin column, so a horse whose birthplace country is flagged Local is Local and anything else is Imported.

Figure 14. A blank Horse. In practice horses arrive through the sync; this form is for the rare record the studbook does not carry.

5. Documents as transactions

A document used to be an attachment field on the Horse — one upload per category, forever. It is now a **Horse Document** record, so a horse can hold as many as its category allows: one Owner ID per co-owner, one covering certificate per season.

Figure 17. An Owner ID. The same five detail fields exist on every document; only the ones its category asks for are shown.

The screenshot shows a web application interface for creating a new horse document. The top navigation bar includes a hamburger menu, the title 'New Horse Document', a 'Not Saved' status indicator, and a 'Save' button. Below the header, there is a form with three input fields: 'Horse *', 'Category *', and 'Attachment *'. The 'Attachment *' field has an 'Attach' button. At the bottom of the form, there is a 'Source' label and a 'Complete' checkbox.

Figure 18. A blank Horse Document. The detail fields stay hidden until a category is picked, because the category is what decides which of them apply.

6. Document categories — the control panel

This is the doctype that replaced the hard-coded rules. Who needs a document, how many they may upload and which details must come with it are all fields here. Changing one takes effect on the next save of any horse; no deployment.

Figure 22. Owner ID: required for both origins and unlimited, so a horse owned by three people can carry three IDs.

7. Events

StudLib records a lifecycle event — a change of owner, a death, an export — and HMS raises it here as a notification. An event is a *notice*, not a state: StudLib writes the death date onto the horse itself, and the horse sync already carries that. Nothing in the event pipeline writes to a Horse, so the two can never corrupt each other.

Figure 26. An import event. **Country** is StudLib's `country_id` on the event, which is only set for imports and exports.

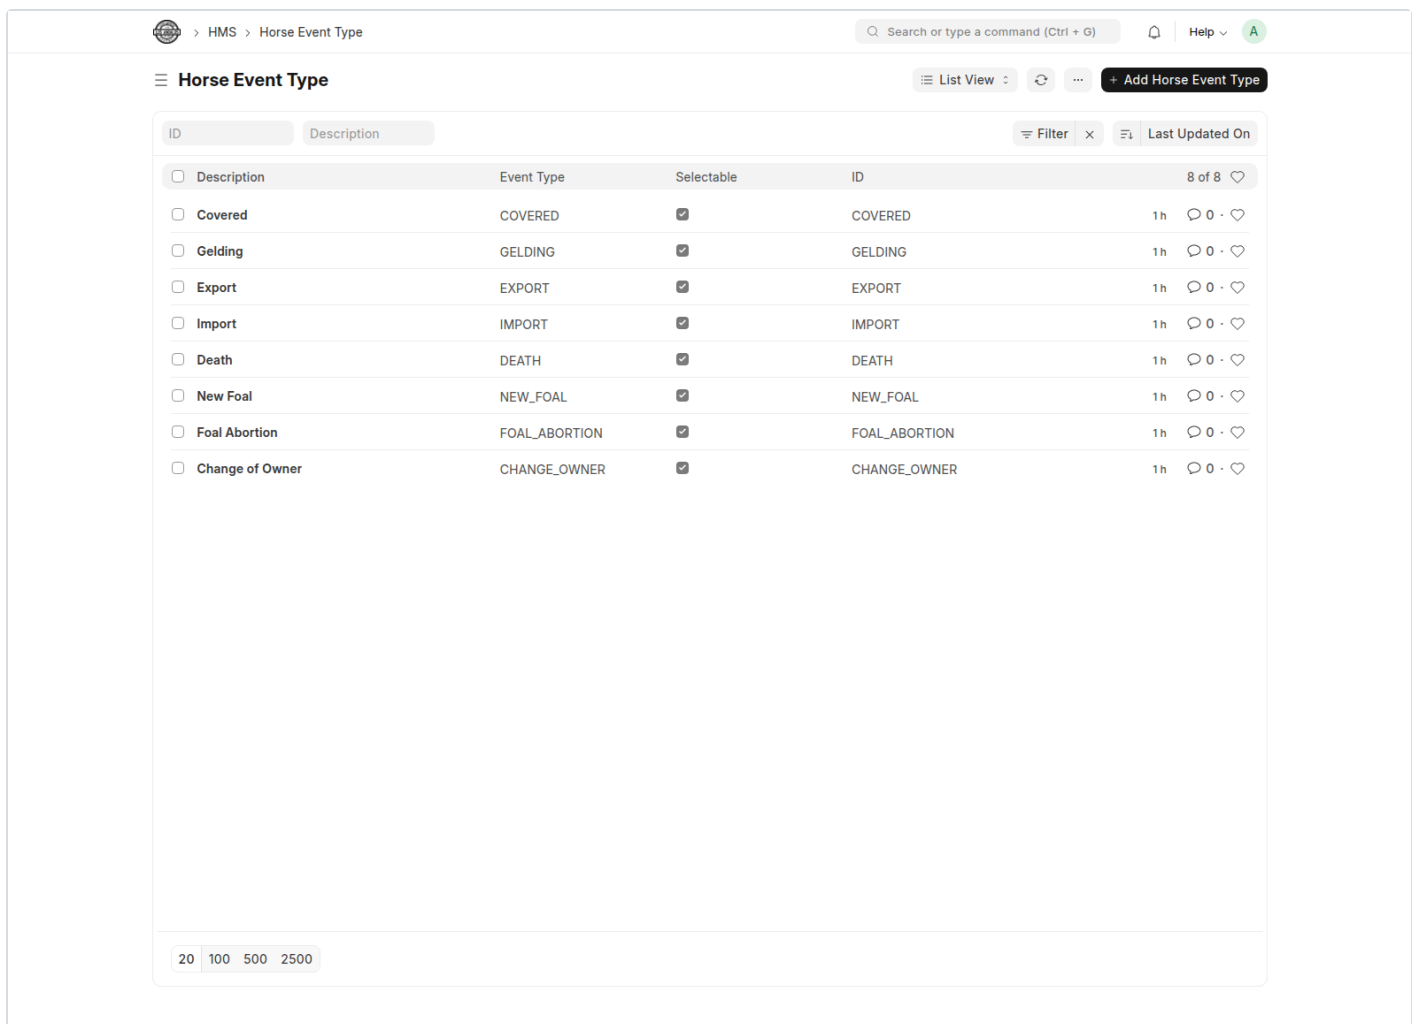

Figure 27. The eight event types StudLib defines. The user guide's Events screen offers only three of them; the rest arrive from the covering and foal registration flows.

8. Owners and studbook reference data

StudLib is normalised: colours, countries and book types are tables of their own, and owners are a directory. The sync mirrors all four before it touches a horse, so the Horse has something to link at.

Internal Note

Never printed on official documents.

Figure 29. One owner. **Business** switches which identifier applies — a company has a business number, a person a national ID. **Suffix** is globally unique and is what disambiguates two owners of the same name on a printed certificate.

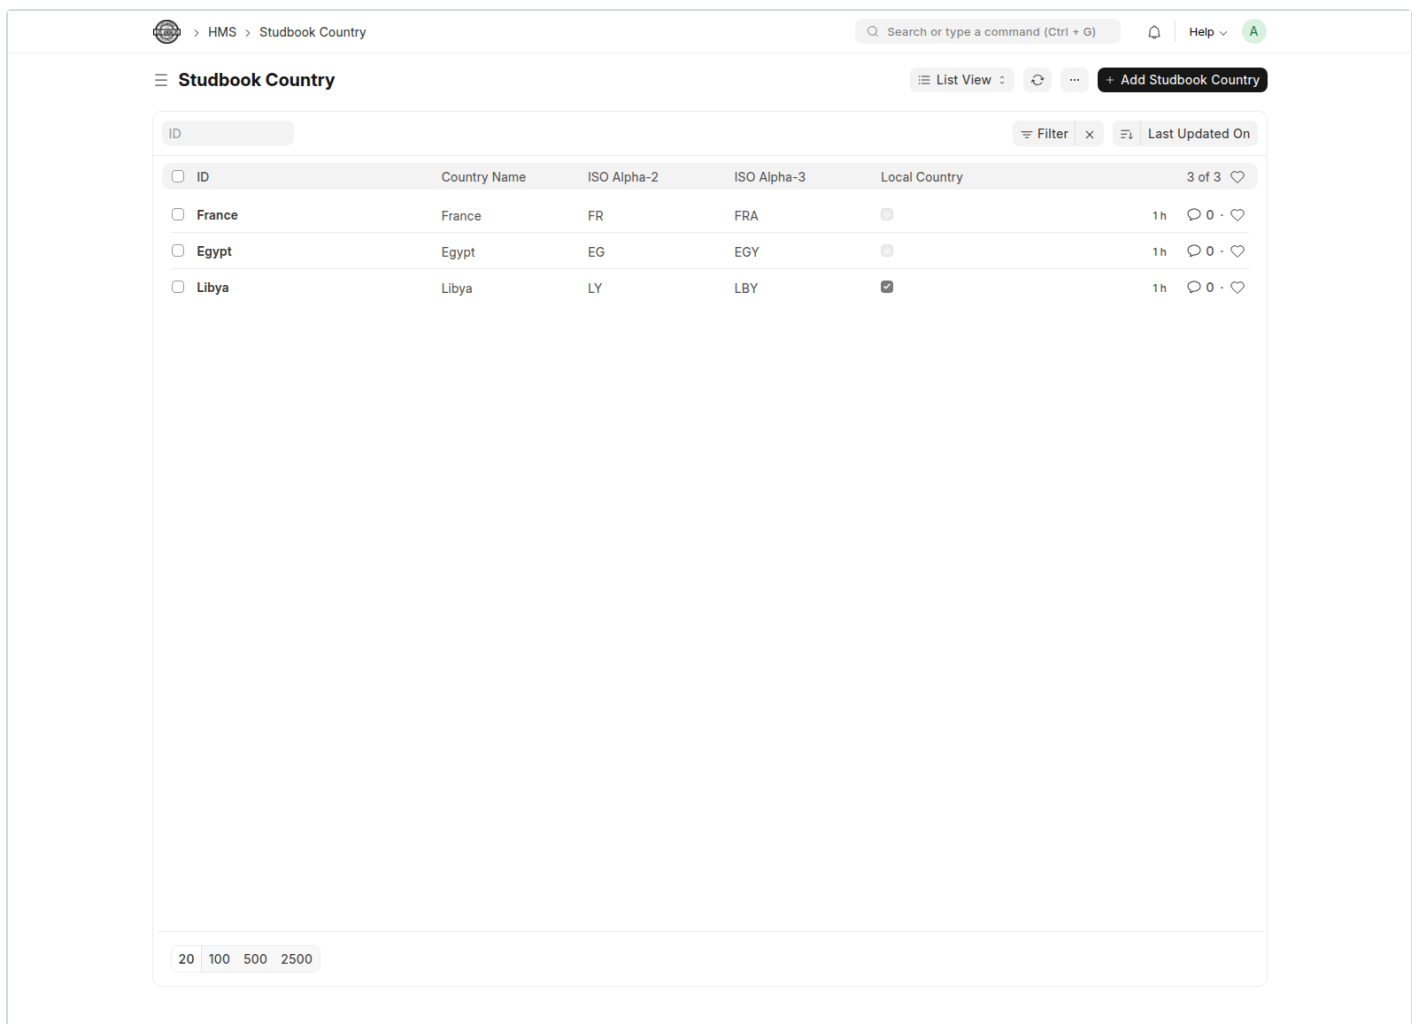

Figure 30. Countries. Exactly one may be flagged **Local Country**; StudLib enforces that with a partial unique index, and it is what makes a horse's origin derivable rather than stored.

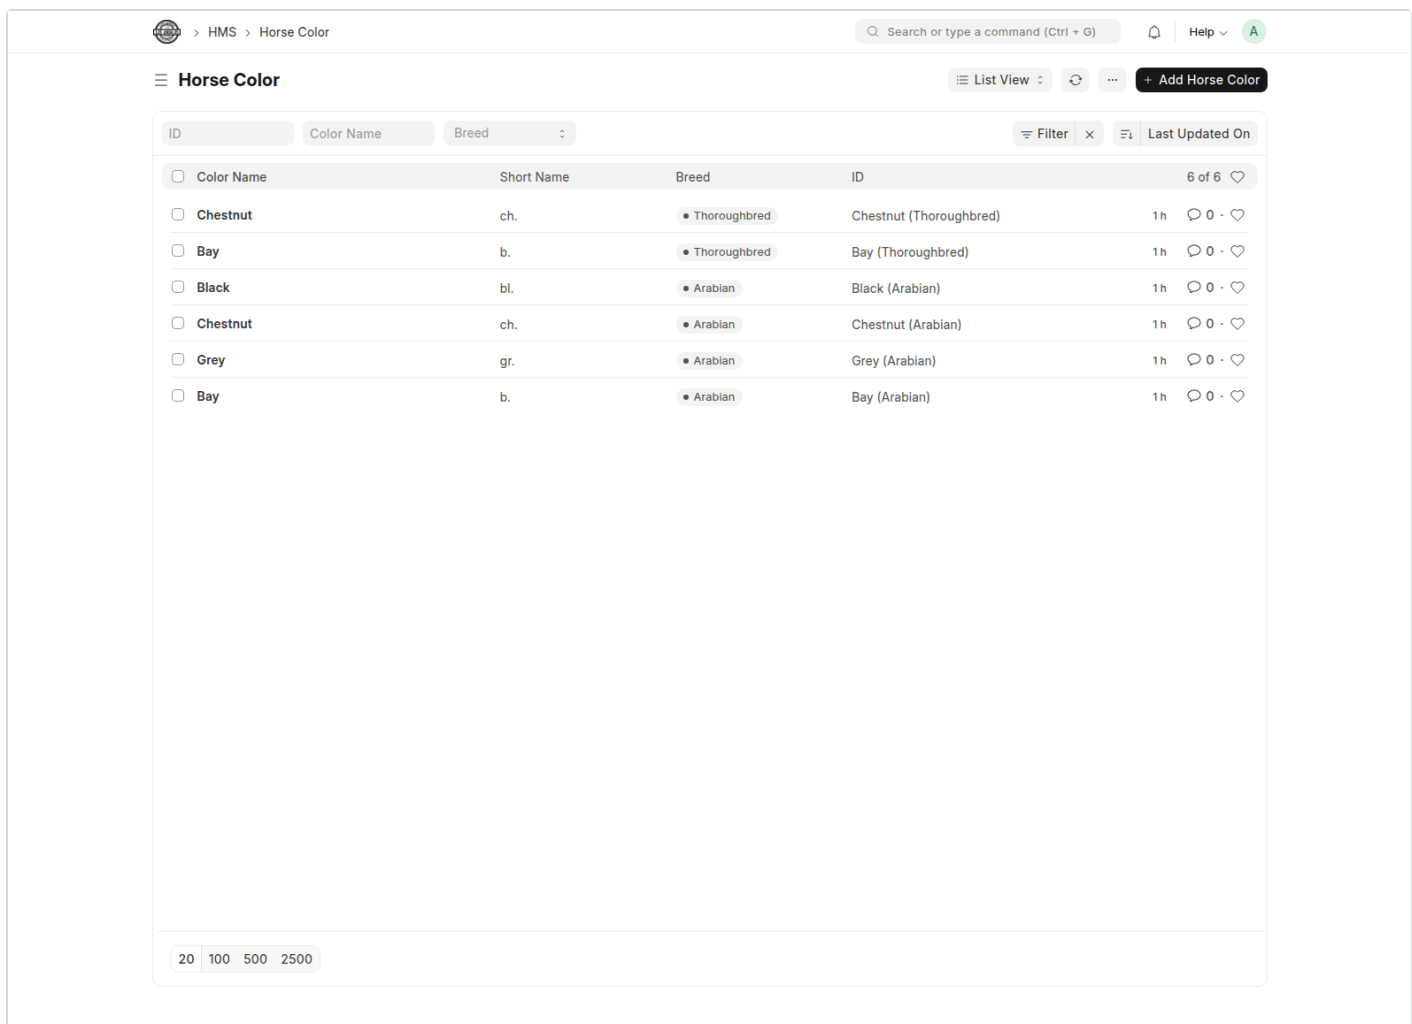

Figure 31. Colours are breed-specific in StudLib — Bay exists once for Arabian and once for Thoroughbred — so the record is named *Colour (Breed)*. **Inheritance Rule** is StudLib's `validation_rule`.

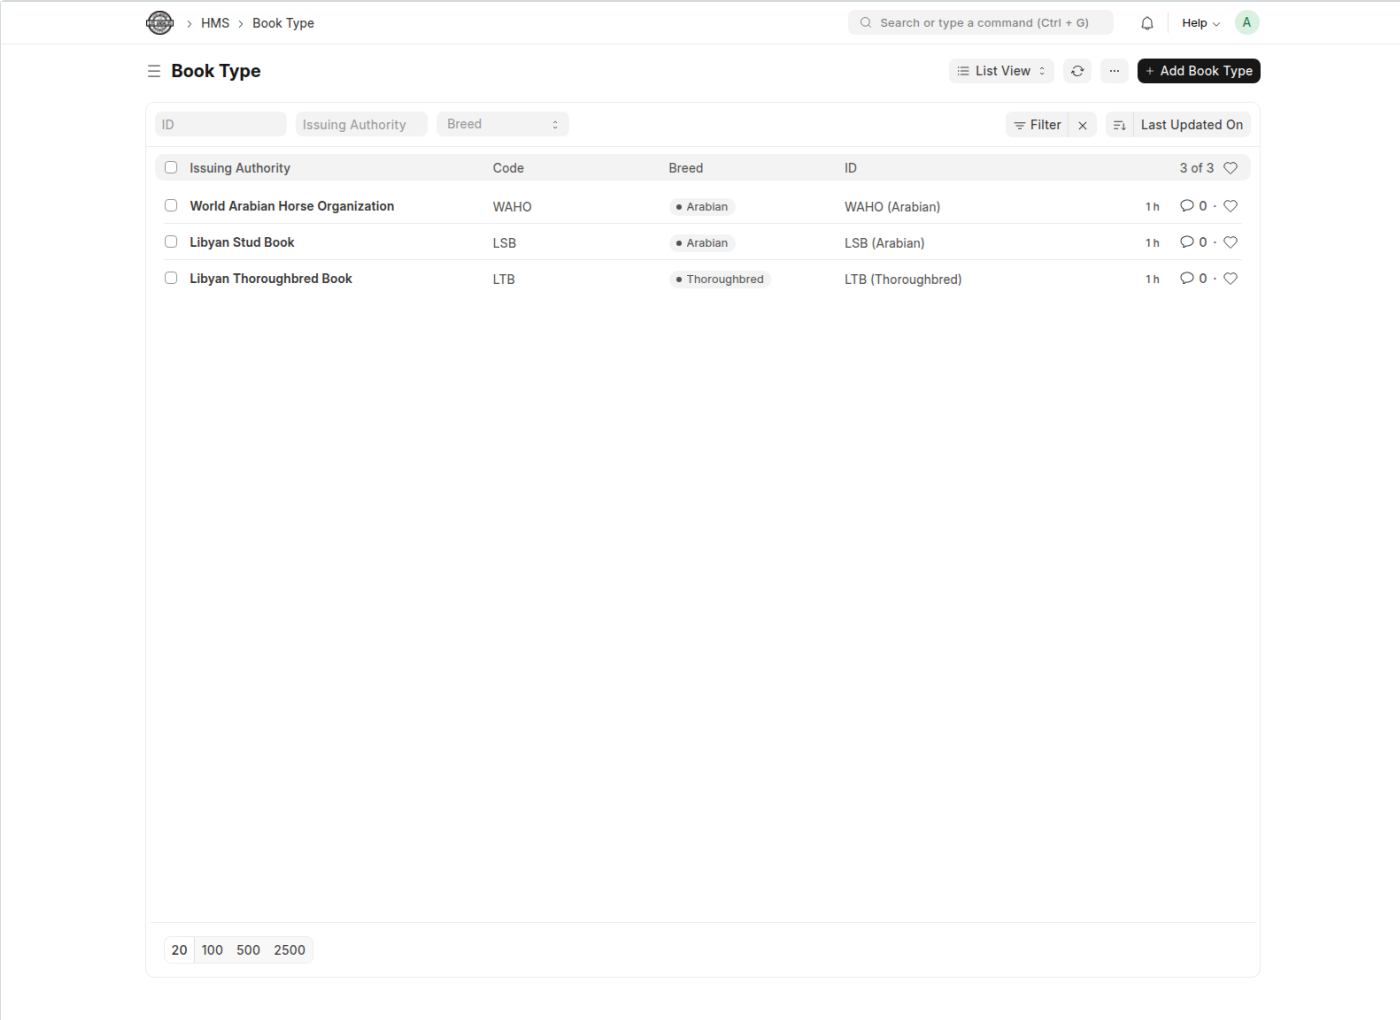

Figure 32. Book types: the studbook sections a horse can be registered in, each belonging to one breed and one issuing authority.

9. The sync and the poll

Both connections live on one settings page. The studbook is read with a read-only Postgres role and HMS never writes back to it.

Figure 33. The studbook connection. **Test Connection** reads a row count and nothing else. **Sync Horses Now** mirrors the reference tables, then upserts every horse. The schedule underneath rewrites a Frappe Scheduled Job, so due times, deduplication and run history all come free. The history table at the bottom keeps the last twenty runs.

HMS — screens and the StudLib link

36 / 49

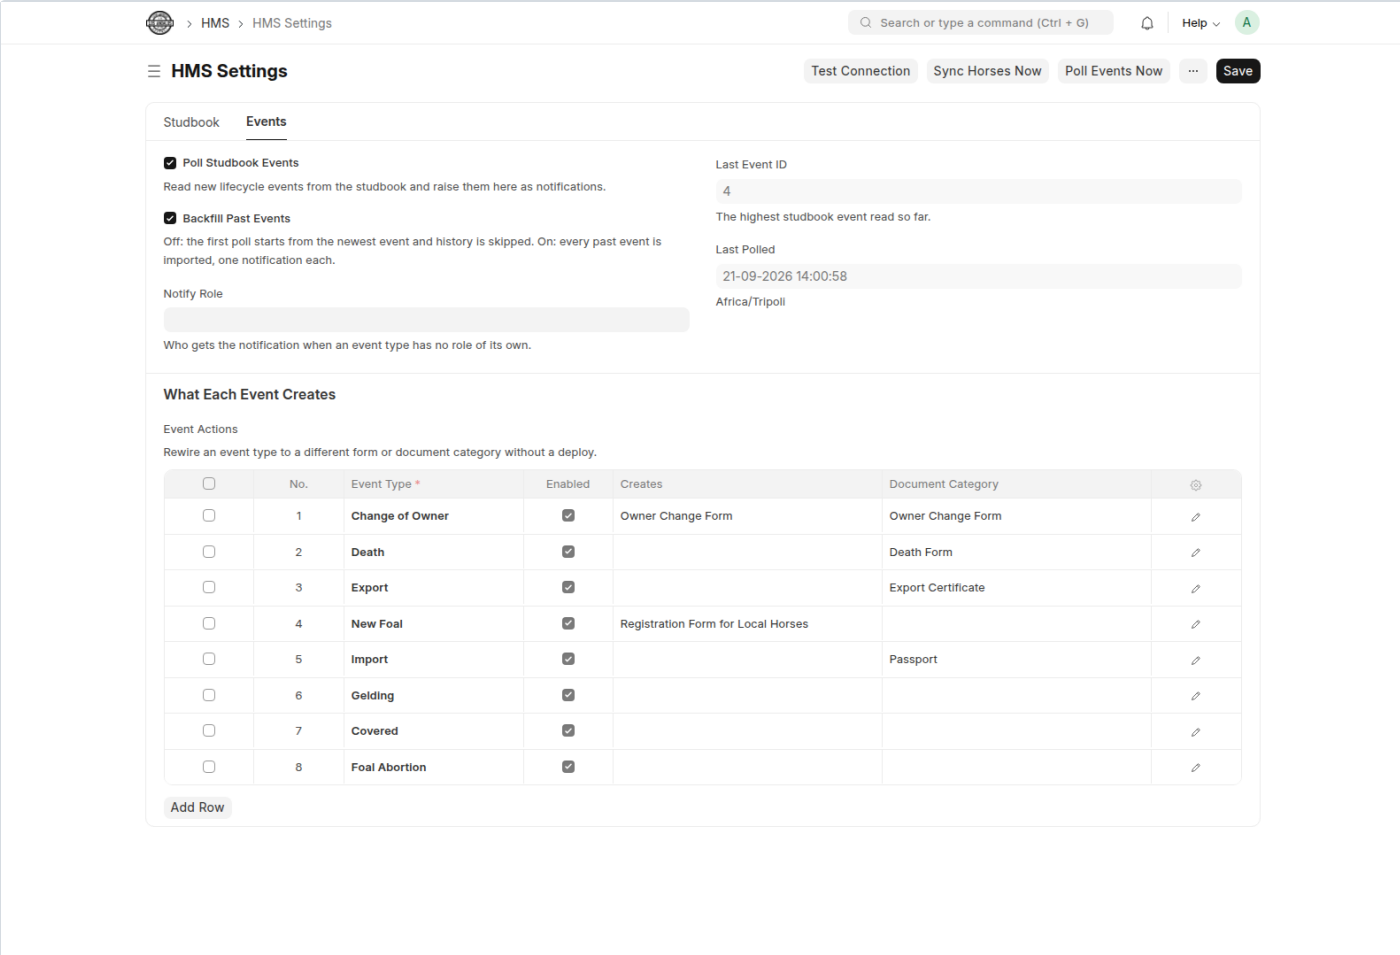

Figure 34. Event polling. **Backfill Past Events** off means the first poll starts from the newest event, so years of history do not each fire a notification. **Event Actions** is what an arriving event turns into: change any row and the next event follows the new rule, with no deployment.

10. The paper forms

These are HMS's own: the studbook knows nothing about them. Each links back to its horse, so it appears in that horse's Connections panel, and each can be created straight from an event.
